Q: How to catch a signal inside an inner class? I'm trying to catch a signal inside a inner class, with a member function: class MyClass: class InnerClass: def foo_bar(self, *args): print 'foo_bar' def inner_foo(self): class InnerClass: def baz(self): self.foo_bar(*args) print 'baz' c = InnerClass() c.baz() I'm getting an "UnboundLocalError: local variable 'c' referenced before assignment" error. Is there any way to bind the scope to the local variable c? (I'm aware of the fact that a binding is performed in the outer function's scope, in this case using the class, but I'm trying to avoid a double binding.) The best solution I could think of is to set c on self (as self.c) within the baz() method, but I would really like to avoid having to use globals. A: The best solution I could think of is to set c on self (as self.c) within the baz() method, but I would really like to avoid having to use globals. You can give up using globals (or, to be more precise, use a method instead). The globals dictionary is never reevaluated, so it'll be populated when your class is defined and it doesn't change in the nested class (e.g. it's not added when you add another method), as long as you use it. Thus, in this particular case, you could use: c.foo_bar(*args) rather than self.foo_bar(*args). You can also use the __init__ method to call a function at the start of your class and give it access to the self instance: class MyClass: def __init__(self):

Reactivity of porphyrins with a one-dimensional inorganic template: a photochemical and redox study on [Fe(II)(6(mu-pz))(2+)] (1) (pz = pyrrole, 4,4'-bipyridine) was synthesized and structurally characterized by X-ray crystallography. The host 1 is constructed from a two-dimensional [Fe(pz)(OH(2))](n)-n (n = 4) framework possessing a hexa-coordinate iron center and an unprecedented metallosupramolecular architecture. The one-dimensional cationic host 1 shows a unique electronic spectra in both the solid state and a dilute toluene solution, with a strong Soret band (407 nm) and a weak Q band (600 nm), which is indicative of an S = 6 ground state. The interaction between the one-dimensional host and a porphyrin was explored by UV-vis and EPR titrations in both a toluene solution and a dilute gas phase. The binding of porphyrin to the host 1 was found to be strongly enthalpy driven. In a dilute toluene solution, porphyrin was found to be "bound" to the host 1 molecule while in the gas phase, a pseudo-tetrahedral adduct was formed. EPR studies were further carried out on the porphyrin-1 complex and revealed the coexistence of both high-spin and low-spin species. The research project will investigate the role of the interferon system in the pathogenesis of idiopathic generalized angiosclerosis (IGAS). It is hypothesized that the pathogenesis of IGAS is associated with defects in the interferon system that result in abnormal antibody formation. The goal is to identify these abnormalities and to determine if an interferon system defect can be identified in the peripheral blood of patients with IGAS. The specific aims are: 1) to study the association between IGAS and abnormalities in the interferon system. An immune response to certain antigens, the presence of which is known to be suppressed by interferons, will be sought in patients with IGAS. The immunization response to some of these antigens will be
